ML0101EN-RecSys-Collaborative-Filtering-movies-py-v1

May 27, 2022

1 Collaborative Filtering

Estimated time needed: **25** minutes

1.1 Objectives

After completing this lab you will be able to:

- Create recommendation system based on collaborative filtering

Recommendation systems are a collection of algorithms used to recommend items to users based on information taken from the user. These systems have become ubiquitous and can be commonly seen in online stores, movies databases and job finders. In this notebook, we will explore recommendation systems based on Collaborative Filtering and implement simple version of one using Python and the Pandas library.

Table of contents

```
<ol>
    <li><a href="https://#ref1">Acquiring the Data</a></li>
    <li><a href="https://#ref2">Preprocessing</a></li>
    <li><a href="https://#ref3">Collaborative Filtering</a></li>
</ol>
```

2 Acquiring the Data

To acquire and extract the data, simply run the following Bash scripts:
Dataset acquired from GroupLens. Let's download the dataset. To download the data, we will use **!wget** to download it from IBM Object Storage.
Did you know? When it comes to Machine Learning, you will likely be working with large datasets. As a business, where can you host your data? IBM is offering a unique opportunity for businesses, with 10 Tb of IBM Cloud Object Storage: Sign up now for free

[1]:
```
!wget -O moviedataset.zip https://cf-courses-data.s3.us.cloud-object-storage.
↪appdomain.cloud/IBMDeveloperSkillsNetwork-ML0101EN-SkillsNetwork/labs/
↪Module%205/data/moviedataset.zip
print('unziping ...')
!unzip -o -j moviedataset.zip
```

```

```

Now you're ready to start working with the data!

3 Preprocessing

First, let's get all of the imports out of the way:

[2]:
```
#Dataframe manipulation library
import pandas as pd
#Math functions, we'll only need the sqrt function so let's import only that
from math import sqrt
import numpy as np
import matplotlib.pyplot as plt
%matplotlib inline
```

Now let's read each file into their Dataframes:

[3]:
```
#Storing the movie information into a pandas dataframe
movies_df = pd.read_csv('movies.csv')
#Storing the user information into a pandas dataframe
ratings_df = pd.read_csv('ratings.csv')
```

Let's also take a peek at how each of them are organized:

```
[4]: #Head is a function that gets the first N rows of a dataframe. N's default is 5.
movies_df.head()
```

```
[4]:    movieId                               title  \
0        1                    Toy Story (1995)
1        2                      Jumanji (1995)
2        3             Grumpier Old Men (1995)
3        4            Waiting to Exhale (1995)
4        5  Father of the Bride Part II (1995)

                                        genres
0  Adventure|Animation|Children|Comedy|Fantasy
1                   Adventure|Children|Fantasy
2                               Comedy|Romance
3                         Comedy|Drama|Romance
4                                       Comedy
```

So each movie has a unique ID, a title with its release year along with it (Which may contain unicode characters) and several different genres in the same field. Let's remove the year from the title column and place it into its own one by using the handy extract function that Pandas has.

Let's remove the year from the **title** column by using pandas' replace function and store it in a new **year** column.

```
[5]: #Using regular expressions to find a year stored between parentheses
#We specify the parantheses so we don't conflict with movies that have years in␣
 ↪their titles
movies_df['year'] = movies_df.title.str.extract('(\(\d\d\d\d\))',expand=False)
#Removing the parentheses
movies_df['year'] = movies_df.year.str.extract('(\d\d\d\d)',expand=False)
#Removing the years from the 'title' column
movies_df['title'] = movies_df.title.str.replace('(\(\d\d\d\d\))', '')
#Applying the strip function to get rid of any ending whitespace characters␣
 ↪that may have appeared
movies_df['title'] = movies_df['title'].apply(lambda x: x.strip())
```

```
/home/jupyterlab/conda/envs/python/lib/python3.7/site-
packages/ipykernel_launcher.py:7: FutureWarning: The default value of regex will
change from True to False in a future version.
  import sys
```

Let's look at the result!

```
[6]: movies_df.head()
```

```
[6]:    movieId                        title  \
0        1                    Toy Story
1        2                      Jumanji
2        3             Grumpier Old Men
```

```
3        4             Waiting to Exhale
4        5   Father of the Bride Part II

                                      genres  year
0  Adventure|Animation|Children|Comedy|Fantasy  1995
1                 Adventure|Children|Fantasy  1995
2                             Comedy|Romance  1995
3                       Comedy|Drama|Romance  1995
4                                     Comedy  1995
```

With that, let's also drop the genres column since we won't need it for this particular recommendation system.

[7]:
```python
#Dropping the genres column
movies_df = movies_df.drop('genres', 1)
```

```
/home/jupyterlab/conda/envs/python/lib/python3.7/site-
packages/ipykernel_launcher.py:2: FutureWarning: In a future version of pandas
all arguments of DataFrame.drop except for the argument 'labels' will be
keyword-only
```

Here's the final movies dataframe:

[8]:
```python
movies_df.head()
```

[8]:
```
   movieId                        title  year
0        1                    Toy Story  1995
1        2                      Jumanji  1995
2        3             Grumpier Old Men  1995
3        4            Waiting to Exhale  1995
4        5  Father of the Bride Part II  1995
```

Next, let's look at the ratings dataframe.

[9]:
```python
ratings_df.head()
```

[9]:
```
   userId  movieId  rating   timestamp
0       1      169     2.5  1204927694
1       1     2471     3.0  1204927438
2       1    48516     5.0  1204927435
3       2     2571     3.5  1436165433
4       2   109487     4.0  1436165496
```

Every row in the ratings dataframe has a user id associated with at least one movie, a rating and a timestamp showing when they reviewed it. We won't be needing the timestamp column, so let's drop it to save on memory.

[10]:
```
#Drop removes a specified row or column from a dataframe
ratings_df = ratings_df.drop('timestamp', 1)
```

```
/home/jupyterlab/conda/envs/python/lib/python3.7/site-
packages/ipykernel_launcher.py:2: FutureWarning: In a future version of pandas
all arguments of DataFrame.drop except for the argument 'labels' will be
keyword-only
```

Here's how the final ratings Dataframe looks like:

[11]:
```
ratings_df.head()
```

[11]:

	userId	movieId	rating
0	1	169	2.5
1	1	2471	3.0
2	1	48516	5.0
3	2	2571	3.5
4	2	109487	4.0

4 Collaborative Filtering

Now it's time to start our work on recommendation systems.

The first technique we're going to take a look at is called **Collaborative Filtering**, which is also known as **User-User Filtering**. As hinted by its alternate name, this technique uses other users to recommend items to the input user. It attempts to find users that have similar preferences and opinions as the input and then recommends items that they have liked to the input. There are several methods of finding similar users (Even some making use of Machine Learning), and the one we will be using here is going to be based on the **Pearson Correlation Function**.

The process for creating a User Based recommendation system is as follows:

- Select a user with the movies the user has watched
- Based on his rating of the movies, find the top X neighbours
- Get the watched movie record of the user for each neighbour
- Calculate a similarity score using some formula
- Recommend the items with the highest score

Let's begin by creating an input user to recommend movies to:

Notice: To add more movies, simply increase the amount of elements in the userInput. Feel free to add more in! Just be sure to write it in with capital letters and if a movie starts with a "The", like "The Matrix" then write it in like this: 'Matrix, The' .

[12]:
```
userInput = [
            {'title':'Breakfast Club, The', 'rating':5},
            {'title':'Toy Story', 'rating':3.5},
            {'title':'Jumanji', 'rating':2},
            {'title':"Pulp Fiction", 'rating':5},
```

```
            {'title':'Akira', 'rating':4.5}
         ]
inputMovies = pd.DataFrame(userInput)
inputMovies
```

[12]:

```
                 title  rating
0  Breakfast Club, The     5.0
1            Toy Story     3.5
2              Jumanji     2.0
3         Pulp Fiction     5.0
4                Akira     4.5
```

Add movieId to input user With the input complete, let's extract the input movies's ID's from the movies dataframe and add them into it.

We can achieve this by first filtering out the rows that contain the input movies' title and then merging this subset with the input dataframe. We also drop unnecessary columns for the input to save memory space.

[13]:

```
#Filtering out the movies by title
inputId = movies_df[movies_df['title'].isin(inputMovies['title'].tolist())]
#Then merging it so we can get the movieId. It's implicitly merging it by title.
inputMovies = pd.merge(inputId, inputMovies)
#Dropping information we won't use from the input dataframe
inputMovies = inputMovies.drop('year', 1)
#Final input dataframe
#If a movie you added in above isn't here, then it might not be in the original
#dataframe or it might spelled differently, please check capitalisation.
inputMovies
```

```
/home/jupyterlab/conda/envs/python/lib/python3.7/site-
packages/ipykernel_launcher.py:6: FutureWarning: In a future version of pandas
all arguments of DataFrame.drop except for the argument 'labels' will be
keyword-only
```

[13]:

```
   movieId                title  rating
0        1            Toy Story     3.5
1        2              Jumanji     2.0
2      296         Pulp Fiction     5.0
3     1274                Akira     4.5
4     1968  Breakfast Club, The     5.0
```

The users who has seen the same movies Now with the movie ID's in our input, we can now get the subset of users that have watched and reviewed the movies in our input.

[14]:
```
#Filtering out users that have watched movies that the input has watched and␣
↪storing it
userSubset = ratings_df[ratings_df['movieId'].isin(inputMovies['movieId'].
↪tolist())]
userSubset.head()
```

[14]:

	userId	movieId	rating
19	4	296	4.0
441	12	1968	3.0
479	13	2	2.0
531	13	1274	5.0
681	14	296	2.0

We now group up the rows by user ID.

[15]:
```
#Groupby creates several sub dataframes where they all have the same value in␣
↪the column specified as the parameter
userSubsetGroup = userSubset.groupby(['userId'])
```

Let's look at one of the users, e.g. the one with userID=1130.

[16]:
```
userSubsetGroup.get_group(1130)
```

[16]:

	userId	movieId	rating
104167	1130	1	0.5
104168	1130	2	4.0
104214	1130	296	4.0
104363	1130	1274	4.5
104443	1130	1968	4.5

Let's also sort these groups so the users that share the most movies in common with the input have higher priority. This provides a richer recommendation since we won't go through every single user.

[17]:
```
#Sorting it so users with movie most in common with the input will have priority
userSubsetGroup = sorted(userSubsetGroup,  key=lambda x: len(x[1]),␣
↪reverse=True)
```

Now let's look at the first user.

[18]:
```
userSubsetGroup[0:3]
```

[18]:
```
[(75,
        userId  movieId  rating
  7507      75        1     5.0
  7508      75        2     3.5
  7540      75      296     5.0
  7633      75     1274     4.5
  7673      75     1968     5.0),
```

```
(106,
       userId  movieId  rating
 9083     106        1     2.5
 9084     106        2     3.0
 9115     106      296     3.5
 9198     106     1274     3.0
 9238     106     1968     3.5),
(686,
        userId  movieId  rating
 61336     686        1     4.0
 61337     686        2     3.0
 61377     686      296     4.0
 61478     686     1274     4.0
 61569     686     1968     5.0)]
```

We will select a subset of users to iterate through. This limit is imposed because we don't want to waste too much time going through every single user.

[19]:
```
userSubsetGroup = userSubsetGroup[0:100]
```

Now, we calculate the Pearson Correlation between input user and subset group, and store it in a dictionary, where the key is the user Id and the value is the coefficient.

[20]:
```
#Store the Pearson Correlation in a dictionary, where the key is the user Id␣
 ↪and the value is the coefficient
pearsonCorrelationDict = {}

#For every user group in our subset
for name, group in userSubsetGroup:
    #Let's start by sorting the input and current user group so the values␣
 ↪aren't mixed up later on
    group = group.sort_values(by='movieId')
    inputMovies = inputMovies.sort_values(by='movieId')
    #Get the N for the formula
    nRatings = len(group)
    #Get the review scores for the movies that they both have in common
    temp_df = inputMovies[inputMovies['movieId'].isin(group['movieId'].
 ↪tolist())]
    #And then store them in a temporary buffer variable in a list format to␣
 ↪facilitate future calculations
    tempRatingList = temp_df['rating'].tolist()
    #Let's also put the current user group reviews in a list format
    tempGroupList = group['rating'].tolist()
    #Now let's calculate the pearson correlation between two users, so called,␣
 ↪x and y
    Sxx = sum([i**2 for i in tempRatingList]) - pow(sum(tempRatingList),2)/
 ↪float(nRatings)
```

```
    Syy = sum([i**2 for i in tempGroupList]) - pow(sum(tempGroupList),2)/
↪float(nRatings)
    Sxy = sum( i*j for i, j in zip(tempRatingList, tempGroupList)) -␣
↪sum(tempRatingList)*sum(tempGroupList)/float(nRatings)

    #If the denominator is different than zero, then divide, else, 0␣
↪correlation.
    if Sxx != 0 and Syy != 0:
        pearsonCorrelationDict[name] = Sxy/sqrt(Sxx*Syy)
    else:
        pearsonCorrelationDict[name] = 0
```

[21]:
```
pearsonCorrelationDict.items()
```

[21]:
```
dict_items([(75, 0.8272781516947562), (106, 0.5860090386731182), (686,

0.29838119751643016), (18509, 0.1322214713369862)])
```

[22]:
```python
pearsonDF = pd.DataFrame.from_dict(pearsonCorrelationDict, orient='index')
pearsonDF.columns = ['similarityIndex']
pearsonDF['userId'] = pearsonDF.index
pearsonDF.index = range(len(pearsonDF))
pearsonDF.head()
```

[22]:

	similarityIndex	userId
0	0.827278	75
1	0.586009	106
2	0.832050	686
3	0.576557	815
4	0.943456	1040

The top x similar users to input user Now let's get the top 50 users that are most similar to the input.

[23]:
```python
topUsers=pearsonDF.sort_values(by='similarityIndex', ascending=False)[0:50]
topUsers.head()
```

[23]:

	similarityIndex	userId
64	0.961678	12325
34	0.961538	6207
55	0.961538	10707
67	0.960769	13053
4	0.943456	1040

Now, let's start recommending movies to the input user.

Rating of selected users to all movies We're going to do this by taking the weighted average of the ratings of the movies using the Pearson Correlation as the weight. But to do this, we first need to get the movies watched by the users in our **pearsonDF** from the ratings dataframe and then store their correlation in a new column called _similarityIndex". This is achieved below by merging of these two tables.

[24]:
```python
topUsersRating=topUsers.merge(ratings_df, left_on='userId', right_on='userId',␣
↪how='inner')
topUsersRating.head()
```

[24]:

	similarityIndex	userId	movieId	rating
0	0.961678	12325	1	3.5

```
1          0.961678   12325         2     1.5
2          0.961678   12325         3     3.0
3          0.961678   12325         5     0.5
4          0.961678   12325         6     2.5
```

Now all we need to do is simply multiply the movie rating by its weight (the similarity index), then sum up the new ratings and divide it by the sum of the weights.

We can easily do this by simply multiplying two columns, then grouping up the dataframe by movieId and then dividing two columns:

It shows the idea of all similar users to candidate movies for the input user:

[25]:
```
#Multiplies the similarity by the user's ratings
topUsersRating['weightedRating'] =␣
↪topUsersRating['similarityIndex']*topUsersRating['rating']
topUsersRating.head()
```

[25]:

	similarityIndex	userId	movieId	rating	weightedRating
0	0.961678	12325	1	3.5	3.365874
1	0.961678	12325	2	1.5	1.442517
2	0.961678	12325	3	3.0	2.885035
3	0.961678	12325	5	0.5	0.480839
4	0.961678	12325	6	2.5	2.404196

[26]:
```
#Applies a sum to the topUsers after grouping it up by userId
tempTopUsersRating = topUsersRating.groupby('movieId').
↪sum()[['similarityIndex','weightedRating']]
tempTopUsersRating.columns = ['sum_similarityIndex','sum_weightedRating']
tempTopUsersRating.head()
```

[26]:

	sum_similarityIndex	sum_weightedRating
movieId		
1	38.376281	140.800834
2	38.376281	96.656745
3	10.253981	27.254477
4	0.929294	2.787882
5	11.723262	27.151751

[27]:
```
#Creates an empty dataframe
recommendation_df = pd.DataFrame()
#Now we take the weighted average
recommendation_df['weighted average recommendation score'] =␣
↪tempTopUsersRating['sum_weightedRating']/
↪tempTopUsersRating['sum_similarityIndex']
recommendation_df['movieId'] = tempTopUsersRating.index
recommendation_df.head()
```

[27]:

```
         weighted average recommendation score  movieId
movieId
1                                     3.668955        1
2                                     2.518658        2
3                                     2.657941        3
4                                     3.000000        4
5                                     2.316058        5
```

Now let's sort it and see the top 20 movies that the algorithm recommended!

[28]:

```
recommendation_df = recommendation_df.sort_values(by='weighted average␣
↪recommendation score', ascending=False)
recommendation_df.head(10)
```

[28]:

```
         weighted average recommendation score  movieId
movieId
5073                                       5.0     5073
3329                                       5.0     3329
2284                                       5.0     2284
26801                                      5.0    26801
6776                                       5.0     6776
6672                                       5.0     6672
3759                                       5.0     3759
3769                                       5.0     3769
3775                                       5.0     3775
90531                                      5.0    90531
```

[29]:

```
movies_df.loc[movies_df['movieId'].isin(recommendation_df.head(10)['movieId'].
↪tolist())]
```

[29]:

```
       movieId                                     title  year
2200      2284                              Bandit Queen  1994
3243      3329                   Year My Voice Broke, The  1987
3669      3759                         Fun and Fancy Free  1947
3679      3769                  Thunderbolt and Lightfoot  1974
3685      3775                            Make Mine Music  1946
4978      5073  Son's Room, The (Stanza del figlio, La)  2001
6563      6672                           War Photographer  2001
6667      6776         Lagaan: Once Upon a Time in India  2001
9064     26801         Dragon Inn (Sun lung moon hak chan)  1992
18106    90531                                      Shame  2011
```

4.0.1 Advantages and Disadvantages of Collaborative Filtering

Advantages

- Takes other user's ratings into consideration
- Doesn't need to study or extract information from the recommended item

- Adapts to the user’s interests which might change over time

Disadvantages

- Approximation function can be slow
- There might be a low amount of users to approximate
- Privacy issues when trying to learn the user’s preferences

IBM SPSS Modeler is a comprehensive analytics platform that has many machine learning algorithms. It has been designed to bring predictive intelligence to decisions made by individuals, by groups, by systems – by your enterprise as a whole. A free trial is available through this course, available here: SPSS Modeler

Also, you can use Watson Studio to run these notebooks faster with bigger datasets. Watson Studio is IBM’s leading cloud solution for data scientists, built by data scientists. With Jupyter notebooks, RStudio, Apache Spark and popular libraries pre-packaged in the cloud, Watson Studio enables data scientists to collaborate on their projects without having to install anything. Join the fast-growing community of Watson Studio users today with a free account at Watson Studio
